Report 12 years ago. #2. An infiltration is injecting local to site (or tooth in our case) that you are trying to numb, to numb only the end of the nerve branch which is supplying that single tooth. So you can give a buccal infiltration in the maxillary region, and the anaesthetic will penetrate the bone (as it is quite thin) and numb that region. A nerve block is when you inject much further up the nerve branch and anaesthetise more of the nerve.

The inferior alveolar and lingual nerve block. The inferior alveolar nerve block is probably the method used by most practitioners for anaesthesia in the adult mandible. The aim of the injection is to deposit local anaesthetic solution close to the mandibular foramen on the medial aspect of the mandibular ramus thus blocking transmission in the inferior alveolar nerve at the point of entry into the bone (Fig 5-3).

Regional block techniques, such as the infraorbital and maxillary nerve blocks, can be used but infiltration is preferred in the maxilla because it is simple and effective. Thus it seems reasonable to assume that where both infiltration and regional blocks are effective the former is preferred.
